Package 'didimputation'

March 9, 2026

Type Package

Title Imputation Estimator from Borusyak, Jaravel, and Spiess (2021)

Version 0.5.1

Description Estimates Two-way Fixed Effects difference-in-differences/event-
study models using the imputation-
based approach proposed by Borusyak, Jaravel, and Spiess (2021).

df_het   *Simulated data with two treatment groups and heterogenous effects*

Description

Generated using the following call: did2s::gen_data(panel = c(1990, 2020), g1 = 2000, g2 = 2010, g3 = 0, te1 = 2, te2 = 1, te3 = 0, te_m1 = 0.05, te_m2 = 0.15, te_m3 = 0)

Usage

df_het

Format

A data frame with 31000 rows and 15 variables:

unit individual in panel data

year time in panel data

g the year that treatment starts

dep_var outcome variable

treat T/F variable for when treatment is on

rel_year year relative to treatment start. Inf = never treated.

rel_year_binned year relative to treatment start, but <=-6 and >=6 are binned.

unit_fe Unit FE

year_fe Year FE

error Random error component

te Static treatment effect = te

te_dynamic Dynamic treatmet effect = te_m

state State that unit is in

group String name for group

---

df_hom   *Simulated data with two treatment groups and homogenous effects*

Description

Generated using the following call: did2s::gen_data(panel = c(1990, 2020), g1 = 2000, g2 = 2010, g3 = 0, te1 = 2, te2 = 2, te3 = 0, te_m1 = 0, te_m2 = 0, te_m3 = 0)

Usage

df_hom

Format

A data frame with 31000 rows and 15 variables:

unit individual in panel data

year time in panel data

g the year that treatment starts

dep_var outcome variable

treat T/F variable for when treatment is on

rel_year year relative to treatment start. Inf = never treated.

rel_year_binned year relative to treatment start, but <=-6 and >=6 are binned.

unit_fe Unit FE

year_fe Year FE

error Random error component

te Static treatment effect = te

te_dynamic Dynamic treatmet effect = te_m

group String name for group

state State that unit is in

weight Weight from runif()

---

did_imputation *Borusyak, Jaravel, and Spiess (2021) Estimator*

Description

Treatment effect estimation and pre-trend testing in staggered adoption diff-in-diff designs with an imputation approach of Borusyak, Jaravel, and Spiess (2021)

Usage

```
did_imputation(
  data,
  yname,
  gname,
  tname,
  idname,
  first_stage = NULL,
  wname = NULL,
  wtr = NULL,
  horizon = NULL,
  pretrends = NULL,
  cluster_var = NULL
)
```

Arguments

`data`	A `data.frame`
`yname`	String. Variable name for outcome. Use `fixest` c() syntax for multiple lhs, e.g. `"c(y1, y2)"`.
`gname`	String. Variable name for unit-specific date of treatment (never-treated should be zero or `NA`).
`tname`	String. Variable name for calendar period.
`idname`	String. Variable name for unique unit id.
`first_stage`	Formula for Y(0). Formula following [`fixest::feols`](#). Fixed effects specified after "|". If not specified, then just unit and time fixed effects will be used.
`wname`	String. Variable name for estimation weights of observations. This is used in estimating Y(0) and also augments treatment effect weights.
`wtr`	Character vector of treatment weight names (see horizon for standard static and event-study weights)
`horizon`	Integer vector of event_time or `TRUE`. This only applies if `wtr` is left as `NULL`. if specified, weighted averages/sums of treatment effects will be reported for each of these horizons separately (i.e. tau0 for the treatment period, tau1 for one period after treatment, etc.). If `TRUE`, all horizons are used. If `wtr` and `horizon` are null, then the static treatment effect is calculated.
`pretrends`	Integer vector or `TRUE`. Which pretrends to estimate. If `TRUE`, all `pretrends` are used.
`cluster_var`	String. Variable name for clustering groups. If not supplied, then `idname` is used as default.

Details

The imputation-based estimator is a method of calculating treatment effects in a difference-in-differences framework. The method estimates a model for Y(0) using untreated/not-yet-treated observations and predicts Y(0) for the treated observations hat(Y_it(0)). The difference between treated and predicted untreated outcomes Y_it(1) - hat(Y_it(0)) serves as an estimate for the treatment effect for unit i in period t. These are then averaged to form average treatment effects for groups of (i, t).

Value

A `data.frame` containing treatment effect term, estimate, standard error and confidence interval. This is in `tidy` format.

Examples

Load example dataset which has two treatment groups and homogeneous treatment effects

```
# Load Example Dataset
data("df_hom", package="didimputation")
```

Static TWFE:

You can run a static TWFE fixed effect model for a simple treatment indicator

```
did_imputation(data = df_hom, yname = "dep_var", gname = "g",
               tname = "year", idname = "unit")
#>      term estimate   std.error conf.low conf.high
#>    <char>   <num>       <num>    <num>     <num>
#> 1:  treat 2.024639 0.03243596 1.961065  2.088214
```

Event Study:

Or you can use relative-treatment indicators to estimate an event study estimate

```
did_imputation(data = df_hom, yname = "dep_var", gname = "g",
               tname = "year", idname = "unit", horizon=TRUE)
#>        term estimate  std.error conf.low conf.high
#>      <char>    <num>      <num>    <num>     <num>
#>  1:       0 2.117232 0.07368419 1.972811  2.261653
#>  2:       1 1.856536 0.07672104 1.706163  2.006909
